Blood flowing through the circulatory system transports nutrients,  
oxygen, and water to cells throughout the body. The journey might  
begin and end with the heart, but the blood vessels reach every vital  
spot along the way. These arteries, veins, and capillaries make for a  
vast network of pipes.

Blood vessels begin to form from the embryonic mesoderm. The  
precursor hemangioblasts differentiate into angioblasts, which give

blood islands scattered throughout the embryo.

Blood consists of plasma, red blood cells, white blood cells, and platelets. Also, the digestive system works with the circulatory system to provide the nutrients the system needs to keep the heart pumping. The cardiovascular systems of humans are closed, meaning that the blood never leaves the network of blood vessels.

Circulatory system - Wikipedia

Larger arteries and veins contain small blood vessels within their walls known as the vasa vasorum—literally “vessels of the vessel”—to provide them with this critical exchange. Since the pressure within arteries is relatively high, the vasa vasorum must function in the outer layers of the vessel or the pressure exerted by the blood passing through the vessel would collapse it, preventing any exchange from occurring.

Pulmonary circulation, system of blood vessels that forms a closed circuit between the heart and the lungs, as distinguished from the systemic circulation between the heart and all other body tissues. On the evolutionary cycle, pulmonary circulation first occurs in lungfishes and amphibians, the first animals to acquire a three-chambered heart.

The heart connects the two major portions of the circulation's continuous circuit, the systemic circulation and the pulmonary circulation. The blood vessels in the pulmonary circulation carry the blood through the lungs to pick up oxygen and get rid of carbon dioxide, while the blood vessels in the systemic circulation carry the blood throughout the rest of our body.
